Outline

history or the problem

Statement of the Problem in Complex Fourier Series

 $\mathfrak{S}L_2(\mathbb{Z})$, congruence subgroup, and modular forms

Yuheng Shi Sum of 4 Squares April 29, 2022

Statement of Problem

- We are interested in the number of ways to write an integer n as sum of four squares, $r_n := |\{(x, y, z, w) \in \mathbb{Z}^4 \mid n = x^2 + y^2 + z^2 + w^2\}|$ for each integer n.
- Lagrange proved the existence of such representation in 1770.

Statement of the Problem in Complex Fourier Series

- Let $q:=e^{2\pi iz}$ where $z\in H:=\{z\in\mathbb{C}|Im\ z>0\}$, let $\Theta(z)=\sum_{n\in\mathbb{Z}}e^{2\pi izn^2}=\sum_{n\in\mathbb{Z}}q^{n2}$ (Note the series converges uniformly on compact subsets of H).
- To calculate r_n is equivalent to calculating coefficients of the Series $\Theta^4(z) = \sum_{n \in \mathbb{N}} r_n q^n$.

Group action of $SL_2(\mathbb{Z})$ and its congruence subgroups on H

•
$$\Gamma := SL_2(\mathbb{Z}) := \{ \begin{pmatrix} a & b \\ c & d \end{pmatrix} \in M_2(\mathbb{Z}) \mid ad - bc = 1 \}$$

- $H := \{z \in \mathbb{C} \mid Im(z) > 0\}$
- Some subgroups of Γ
 - principle subgroup of level N, $\Gamma(N) := \{ \begin{pmatrix} 1 & 0 \\ 0 & 1 \end{pmatrix} \mod N \}$
 - $\begin{array}{l} \bullet \ \, \Gamma_1(\textit{N}) := \{ \begin{pmatrix} 1 & * \\ 0 & 1 \end{pmatrix} \; \text{mod} \; \textit{N} \} \; \text{(a congruence subgroup of level N)} \\ \bullet \ \, \Gamma_0(\textit{N}) := \{ \begin{pmatrix} * & * \\ 0 & * \end{pmatrix} \; \text{mod} \; \textit{N} \} \; \text{(a congruence subgroup of level N)} \\ \end{array}$
- We will be interested in the subgroup $\Gamma_0(4)$
- Group action of $SL_2(\mathbb{Z})$ (and its subgroups) on H:

$$\begin{pmatrix} a & b \\ c & d \end{pmatrix} \cdot z = \frac{az+b}{cz+d}$$
(Fractional Linear Transformation)

Modular/Cusp form for congruence subgroup of level N

Let $q_N=e^{2\pi iz}$. f(z) be holomorphic on H, and let $\Gamma'\subset \Gamma$ be a congruence subgroup of level N. We call f a modular form of weight k for Γ' $(M_k(\Gamma'))$ if $\forall \gamma=\begin{pmatrix} a & b \\ c & d \end{pmatrix}\in \Gamma'$, $f(\gamma z)=f(z)(cz+d)^k$, and if $\forall \gamma_0=\begin{pmatrix} a_0 & b_0 \\ c_0 & d_0 \end{pmatrix}\in \Gamma$, the q_N -expansion of $f(\gamma_0z)(c_0z+d_0)^{-k}$ has 0 coefficients in negative powers (This is equivalent to saying that this function goes to a finite number as $z\to i\infty$). Furthermore, we say f is a cusp form of weight k $(S_k(\Gamma'))$ if the q_N -expansion has 0 coefficients in non-positive powers (This is equivalent to saying that this function goes to 0 number as $z\to i\infty$)

$M_2(\Gamma_0(4))$

- It can be shown that $\Theta^4 \in M_2(\Gamma_0(4))$, and $F := \sum_{n \text{ odd}} \sigma_1(n)q^n \in S_2(\Gamma_0(4))$. It can also be shown that $\dim_{\mathbb{C}}(M_2(\Gamma_0(4))) = 2$, thus Θ^4 , F is a basis for $M_2(\Gamma_0(4))$.
- By defining Hecke operators T_n on $M_2(\Gamma_0(4))$, we can show that for n odd, T_n is just multiplication by $\sigma_1(n)$, and Θ^4 is eigenvector of T_n with eigenvalue $\frac{1}{8}r_n$. Thus $r_n = 8\sigma_1(n)$.

Yuheng Shi Sum of 4 Squares April 29, 2022 7/8

The Result

•
$$r_n = \begin{cases} 8\sigma_1(n), n \text{ odd} \\ 24\sigma_1(n_0), n = 2^k n_0, 2 \nmid n_0, n \text{ even} \end{cases}$$
